APPLE OF THE EYE

• The US-based company has more than tripled its share of India output

■ APPLE ■ SAMSUNG ■ VIVO ■ OPPO ■ XIAOMI ■ OTHERS
SOURCE COUNTERPOINT RESEARCH

includes televisions and air-conditioners. The Chinese appliances and electronics maker started local production of room air-conditioners in Sri City, Andhra Pradesh, in 2026. Much like in smart electronic gadgets, appliances too have considerable electronic components. These include microcontrollers, PCBs and sensors that handle power regulation,

signal processing and control logic, among other things. “While China continues to be a large-scale global manufacturing hub for us, local production in India enables close alignment with domestic demand, faster supply-chain response and ability to customise products,” says Pankaj Rana, CEO, Hisense India.

That logic is now spreading across categories once seen as peripheral to the smartphone narrative: hearables, wearables, smart bulbs, laptops, tablets, telecom equipment and other critical electronics parts. India is becoming a fast-growing hub not only for standalone gadgets but also for electronics inside consumer durable and connected products. “The conversation has shifted from design software alone to manufacturing applications that help machines talk to one another, automate production planning, optimise logistics and simulate factory operations using virtual twins,” says Deepak NG, managing director, Dassault Systèmes India. Dassault Systèmes provides software for various manufacturing sectors, including aerospace and life sciences. Speed and quality, Deepak argues, are the two non-negotiables if India wants to compete globally. China’s advantage has not only been cost; it has been the ability to deliver with consistency and speed. Indian manufacturers cannot match that through conventional methods alone. They need technology, software, digital production systems, simulation tools and process control.

As Apple and the wider ecosystem gear up to scale manufacturing in India, it will also have to address a few challenges. First is the lack of localisation. India has become consistent in assembling finished goods, but that is only one part of the value chain. The more technology-intensive the component, the more likely it is to be imported. Semiconductor fabrication for cutting-edge chips that go into smartphones, computers and other hi-tech electronics will need to scale up. Display panels, image sensors and advanced camera systems
