

critical industrial components, where cargo value justifies air movement but volumes never justified an airport. Add mining in roadless interiors, renewable-energy farms needing turbine spares and e-commerce consolidation, and the pattern is clear — autonomous heavy-lift aircraft are quiet infrastructure for developed-economy backbone industries.

“Cost per kilogram-kilometre is the only metric that ultimately matters in logistics — and autonomy is how you win it.”

What India must get right

The technology is arriving faster than most planners expect. Whether India leads depends on choices being made now. Three stand out.

- **Airspace as infrastructure.** The Drone Rules 2021 and Digital Sky were a strong start. The next step is routine beyond-visual-line-of-sight corridors for cargo aircraft — treated with the same seriousness as a highway corridor, because that is what they are.

- **Backing indigenous deep tech.** Production-linked incentives and defence indigenisation lists have created real momentum. The multiplier comes when Indian operators — logistics majors, e-commerce platforms, state governments — become anchor customers for Indian platforms, the way Indian telecom scaled on Indian demand.

- **Talent density.** Autonomous aviation sits at the intersection of aerospace, robotics, and AI. India produces world-class engineers in all three; the mission now is to give them world-class problems to solve at home.

Why deep tech needs deep industry

Few deep-tech companies in aerospace and defence make the leap from prototype to industrial reality. Engineering is only the first barrier. What follows is harder: patient capital for multi-year certification cycles, financing manufacturing at scale, supply chains built over decades, and the credibility to sit across the table from governments and armed forces. Brilliant technology dies in that gap every year.

Telebortix was built to close it — a deliberate fusion of deep technology and deep industry, pairing a research-led engineering core with one of India's enduring business houses.

On the technology side, my path runs through robotics and autonomy research, including work at Carnegie Mellon University, before returning to build in India. Autonomous flight is fundamentally a robotics problem — perception, state estimation and decision-making under uncertainty — demanding founders who understand the codebase and flight-test data. That conviction shapes how we

Founder & Chairman at Enarr Group

hire and what we build ourselves.

On the industry side, Telebortix is anchored by Dr. Shhyam R. Singhania and Mr. Padam R. Singhania of the ENARR Group, carrying forward the 125-year business legacy of Sir P.G. Singhania. Dr. Shhyam Singhania, Founder and Chairman of ENARR Capital, brings over three decades of leadership across industry, textiles, media and financial services. Mr. Padam Singhania, who leads ENARR's international financial verticals across structured finance and supply-chain trade finance, brings the capability capital-intensive aerospace manufacturing lives or dies by — structuring long-horizon finance and building disciplined industrial supply chains.

“Deep tech gets you the aircraft. Deep industry gets you the industry.”

That combination is our sharpest differentiator. Many drone companies can fly a demonstrator. Far fewer can finance a production line, hold a supply chain through scale-up, and earn the confidence of defence establishments and institutional investors. Aerospace is not a software category; it is an industrial endeavour requiring capital patience measured in years and manufacturing depth measured in decades. Founders who understand the physics, backed by a house that understands industry — that is why we are building for an enduring Indian aerospace company.

The view from 2047

Picture India at 100. A horticulture cluster in Himachal flying produce to a rail-head the same morning it is picked. An island clinic in the Andamans restocked from Port Blair an hour earlier. A flood-hit district in Assam supplied while its roads are underwater. A manufacturing belt in Bundelkhand connected to national supply chains without waiting a decade for expressways. None requires science fiction. It requires aircraft on Indian drawing boards and test ranges, regulation treating

VC & MD at Enarr Group

the low-altitude sky as economic infrastructure, and the conviction that this industry should be built here.

India missed the first aviation revolution and spent a century buying aircraft from others. The autonomous aviation revolution is different — it is young enough, and India is strong enough, to help define it. At Telebortix, that is the future we are building toward. By India@100, we intend for the question ‘who builds the world's autonomous cargo aircraft?’ to have an obvious answer.

TELEBORTIX INNOVATIONS — AT A GLANCE

Founded: 2024, Delhi-NCR | Focus: Autonomous UAV systems for Indian Armed Forces and dual-use commercial markets

Defence: Active programmes with premier Indian Army establishments under the defence innovation framework; seven-platform portfolio from nano and tactical systems to heavy-lift logistics aircraft, with field trials through 2026

Technology: Indigenous autonomy, GNSS-denied navigation and multi-vehicle coordination stack — free of foreign licensing encumbrances

Flagship: BA-75 heavy-lift VTOL for high-altitude sustainment, middle-mile cargo, offshore energy logistics and disaster response; prototype flight testing planned for 2026

Web: www.telebortix.com

Suryansh Saxena is the Founder & CEO of Telebortix Innovations, a Delhi-NCR-based defence and dual-use aerospace company. A robotics researcher with a background at Carnegie Mellon University, he leads Telebortix's work on autonomous flight, GNSS-denied navigation and heavy-lift VTOL aircraft. Telebortix is anchored by Dr. Shhyam R. Singhania and Mr. Padam R. Singhania of the ENARR Group, carrying forward the 125-year business legacy of Sir P.G. Singhania.
