

If we look at the energy transition, I think India is well-positioned... [like for example] in the solar value chain

such as pharma and electronics. For instance, in the case of Apple iPhones, India has gone from contributing nothing to now accounting for 13–15% of production, with expectations of reaching 30–35%. Similarly, there are

significant investments in the solar and battery value chains. The Tata group, for example, has made major commitments, not just in electronics and semiconductor fabrication, but also in military aircraft production. In the

defence sector, the share of domestic private sector production has substantially increased, leading to a significant reduction in defence imports.

For example, if you look at the pharma sector and bulk drugs, our share of

exports has increased significantly, while the share of imports has declined. In the auto components and the broader automotive ecosystem, we used to run a trade deficit. However, we have now transitioned to a situation of surplus. Many components from India are now globally recognised and accepted, which has boosted our export share.

That said, all these developments have not yet moved the needle as much as we would like, in terms of the share of manufacturing in GDP.
