TRY IMAGINING THIS. The year is 2047. Some of the top conglomerates and public sector firms are carbon neutral. India has a green power grid fed by renewable energy, unlike now when coal dominates. A majority of two- and four-wheelers running on Indian roads are electric powered. And Indians can breathe clean air throughout the year.

That's not a stretch if India sticks to the road map for achieving net-zero emissions by 2070. That plan is premised on six elements—expanding renewable energy capacity; improving access to alternative clean energy sources such as nuclear energy, green hydrogen, fuel cells, and biofuels; increasing energy efficiency; rational utilisation of fossil fuel resources; industrial decarbonisation; and an optimum energy mix complementing national development scenarios.

But getting there requires a vast improvement in the infrastructure. This will require heavy investment not just from the government but from the private sector as well.

CAPACITY BUILDING

To ensure steady progress towards net zero, the country needs to take it one step at a time. In a recent report, Climake, an or-

Reduce carbon emissions by 1 billion tonnes by 2030 from 2.88 giga tonnes in 2021

Reduce carbon emission intensity by 45% by 2030 from the 2005 level

Through these measures achieve net-zero carbon emissions by 2070
