

T

RAINS FASTER THAN planes? Yes, you read it right, and it could be a reality soon. China recently tested magnetic levitation (Maglev) technology trains running at 600 km/h. India

is experimenting with 1,100 km/h hyperloop technology, which can cover the Delhi to Mumbai distance in just over an hour. Hyperloop uses capsules supported by an air-bearing surface within a low-pressure tube.

A 410-metre-long hyperloop test tube is already operational in IIT Chennai. The government is now planning the development of a 50-km hyperloop corridor—the longest in Asia—for commercial transport. This will completely change train travel.

This is part of a series of futuristic infrastructure projects related to urban development, smart

mobility, energy transition, and social and digital infrastructure that India is exploring keeping in mind its aspiration to become a developed economy by 2047.

Nilachal Mishra, Partner and Head, Government & Public Services, KPMG, says by 2047, India is expected to undergo a significant transformation in how people and goods move, how cities grow, and how energy is produced and consumed.

“Overall, India’s infrastructure future will likely be shaped by a blend of technology, inclusivity, and sustainability with global learnings adapted to domestic needs,” he tells *Business Today*. However, these goals are constrained by a significant infrastructure financing gap, exceeding 5% of its GDP, according to the World Bank.

Despite a substantial increase in public
