

40 | power rectifiers, electrolysers, and skill sets of the people. That's not the biggest business yet because these are early days. But we know this is a new area where we need to invest early so that it's significant some years from now.

Q: How do you look at global supply chain challenges and the geopolitical situation?

A: One thing we talk about is serving every market with local sourcing and manufacturing. This reduces risk. Considering the geopolitical situation, we are doing less cross-country trading. That's what we do in India as well; we localise as much as possible. One aim is, of course, remaining ahead in a highly competitive market such as India. The second is to remain resilient by being less dependent on imports. A good example is high-efficiency motors that need permanent magnets. We have designed our permanent magnet using a specially designed rotor that uses only steel. It's smart engineering that nullifies the need for permanent magnets, reducing the dependence on imports, the majority of which come from China.

Q: What do you think about India's journey so far vis-à-vis other key markets?

A: The challenge here is to produce high technology but at 80% lower cost than somewhere else. And you need to think completely differently. So, the challenge

“The challenge here is to produce high technology but at 80% lower cost than somewhere else”

is not always to solve a problem but solve it at a cost that is unthinkable when you start but then, very often, you're able to do it. It's not that India is different. China is highly competitive as well and it's not easy to compete there either or in Germany for that matter. But this is how you need to be the best at your game.

Q: How is your last purchase, Gamesa, helping ABB?

A: It's strengthening our position in renewables. We are strong in power semiconductors and power conversion. Both Siemens and Gamesa have produced wind-mills in the past that need service and maintenance. So, we will be the partner for spare parts for that huge installed base. We are also looking at new converters. This technology is used not only in wind and solar but also in green hydrogen and battery energy storage. **BT**
